

Staying Power: The Individual Effects of the H-1B Visa Lottery

Amy Kim

Princeton University, Department of Economics

Midwest Economics Association: SOLE

March 22, 2026

Motivation

- Large literature: effects of immigration on U.S. labor market [Card 1990; Borjas 2003; Ottaviano and Peri 2012]
- Common setting: **H-1B visa program**
 - Tied to employer-worker pair; allocated *via lottery*
 - Recent concerns about fraud + rising demand → new \$100k fee
- Existing literature: GE, local labor market, firm effects [Bound et al. 2017; Doran et al. 2022; Mahajan et al. 2024]
 - How are firms using the lottery in practice?
 - What happens to workers who lose the lottery?
- **This Project:** Estimating **worker-level effects** of winning H-1B lottery

Linkage Strategy

Empirical hurdles in estimating worker-level H-1B effects:

- ① Lack of information on H-1B lottery losers or activity outside U.S.
 - **This Project:** New data on universe of H-1B applicants + LinkedIn profiles
- ② No personal identifiers (name, ID number) in H-1B data
 - **This Project:** Probabilistic linking to LinkedIn profile data across many sparse fields (including firm)
- ③ Don't observe workers' outcomes unless they win visa
 - Traditional view of H-1B: firm hires worker if they win visa, otherwise don't
 - In reality, majority of H-1B applicants are *already working at firm* on a different temporary visa
 - New view of H-1B: firm employs worker who stays if they win visa, otherwise leaves
 - **This Project:** Link by subsetting to workers already at firm at time of application

Result: Individual-level panel data on 65k H-1B lottery applicants

This Paper

Research Question: What are the effects of winning the H-1B lottery on the individual worker?

- ① Estimate effects of lottery win on indiv. outcomes
 - **Preview:** Winning $\uparrow$ U.S. retention by 1.16 pp (1.2%); firm retention by 2.64 pp (3.6%) 1 yr post-lottery
 - Suggestive evidence of job stagnation for winners (stay at same firm but less likely to get promotion)
 - Losers do not reallocate to new education
- ② Investigating robustness and heterogeneity: why are effects small?
 - I investigate various channels: measurement error & OPT fallback seem to matter, but don't fully account for small effects

This Paper

Research Question: What are the effects of winning the H-1B lottery on the individual worker?

- ① Estimate effects of lottery win on indiv. outcomes
 - **Preview:** Winning $\uparrow$ U.S. retention by 1.16 pp (1.2%); firm retention by 2.64 pp (3.6%) 1 yr post-lottery
 - Suggestive evidence of job stagnation for winners (stay at same firm but less likely to get promotion)
 - Losers do not reallocate to new education
- ② Investigating robustness and heterogeneity: why are effects small?
 - I investigate various channels: measurement error & OPT fallback seem to matter, but don't fully account for small effects

Empirical Puzzle: How are lottery losers managing to stay?

4. Results
5. Conclusion

What is an H-1B Visa?

- Temporary work visa (6 years) for workers in 'specialty occupations'
 - Requires highly specialized knowledge + at least a bachelor's degree
- Employer-sponsored: firm must apply on worker's behalf
 - Portable between employers, but no self-sponsorship
 - Employer can sponsor worker for green card (but application tied to employer)
- Capped at 85,000 visas per year since 2004
 - 65,000 regular cap + 20,000 advanced degree exempt (ADE) for U.S. M.A.+
 - Demand has exceeded cap every year since 2013
- Since 2013: visas allocated via **lottery** each spring
 - Results in April, visa valid starting October

The H-1B Lottery: Key Facts

- FY2021: USCIS moved to electronic registration (\$10 fee vs. \$500+ full petition)
 - **Critical for this paper:** USCIS began keeping records of lottery *losers*
 - Prior data: only winners observed
- Electronic system enabled fraud: duplicate applications via different employers
 - Outsourcing/staffing firms 'overapply' — treat workers as interchangeable
 - I exclude firm-years with any duplicate applicants
- Win rates: ~35–40% for regular lottery
 - ADE applicants entered into separate lottery first (higher win rate)
- **Identification:** within firm-year, lottery selection is as good as random

Optional Practical Training: The Key Bridge

- F-1 (student) visa holders may work after graduation under OPT
 - Standard OPT: 12 months of authorized employment
 - STEM extension: up to 36 months total for STEM graduates
- OPT has become dominant pathway into H-1B
 - 50–70% of recent H-1B approvals go to workers already in U.S.
 - 94% of F-1→H-1B transitions use OPT
- **Common trajectory:** graduate → OPT → apply for H-1B each spring (up to 3 tries)
 - Worker already employed at sponsoring firm during OPT
 - Firm retains worker if they win; worker faces uncertainty if they lose
- **Key insight:** pre-lottery employment relationship enables linkage

Outline

1. Introduction
2. Background and Context
3. Data and Linkage
4. Results
5. Conclusion

Data Sources

- **H-1B Application Data** (FOIA via Bloomberg, 2020–2023)
 - All applicants: country of birth, birth year, sex, employer name/location
 - Winners only: current visa type, education level/field, job title/salary
 - 1.8 million applications; first dataset with both winners and losers
- **Revelio Labs LinkedIn Data**
 - Profiles (894m individuals): full name, education history, work history
- **Challenge:** H-1B data is deidentified — no names, no unique identifiers
 - ‘Needle in a haystack’ problem without employer
- **Key insight:** restrict candidates to workers already at sponsoring firm before lottery

Overview of Linkage Strategy

- ① **Employer crosswalk:** fuzzy match H-1B firms to Revelio firms (93% match rate)
 - Exclude firm-years with 10+ applications or any duplicate applicants
 - Iterative process: deterministic matching → LLM review
- ② **Revelio imputation:** estimate country of birth, birth year, sex
 - For now: simple ML model using Wikipedia data (name2nat) + deterministic rules
 - Future: LLM-based review using full profile information (description, etc.)
- ③ **Candidate scoring:** for each applicant, pick 'close-enough' candidates matches *working at sponsoring firm* at time of lottery
 - Restrict to LinkedIn users with US education (OPT eligible) but no US high school (not native)
 - Score candidates on match quality

Result: weighted panel of 167,598 linked applications

Sample Variants

- **Baseline:** keep unrestricted sample, collapse at application level, drop singleton firms (FEs not identified) ($N = 70,580$)
- **One-to-one (preferred):** optimal bipartite matching ($N = 64,781$)
 - Each applicant assigned to at most one Revelio candidate (and vice versa) within a lottery year
- **Strict (Q25 / Q50 / Q75):** score threshold samples
 - Restrict to applicants whose best match score exceeds the 25th, 50th, or 75th percentile
 - Higher confidence matches; trade off sample size for precision
- **Rare Country:** exclude high-multiplicity countries ($N = 10,440$)
 - Drop applicants from Southern Asia, East Asia, UK, Canada, Australia
 - Lower candidate pool multiplicity $\rightarrow$ sharper individual identification

Can evaluate match quality using H-1B winners: for now overly strict [Match Quality Table](#)

1. Introduction
2. Background and Context
3. Data and Linkage
4. Results
5. Conclusion

Empirical Specification

For applicant i at firm c in lottery year t , estimate:

$$y_{ict}^s = \beta_0 + \beta_1 \text{Win}_{ict} + \beta_2 \text{ADE}_{it} + \gamma_{ct} + \varepsilon_{ict}^s$$

- Win_{ict} : lottery selection indicator
- ADE_{it} : advanced degree exempt (separate, higher-odds lottery)
- γ_{ct} : firm-by-lottery-year fixed effects
- Outcomes measured s years post-lottery; weights from probabilistic linkage
- Standard errors clustered by firm
- Alternate specification: include $\text{Win} \times \text{ADE}$ interaction (results similar)

Identification: within firm-year, lottery selection random conditional on ADE

Outcome Variables

- **Location:** In U.S., in home country, in non-U.S. non-home country
- **Employment:** still at same firm, new position conditional on same firm (proxy for promotion)
- **Education:** new education (possible channel for staying in U.S.)

Winning the Lottery ↑ U.S. Presence...

	In U.S. (1)	In home ctry (2)	Non-US non-home (3)	Same firm (4)	New pos. (cond.) (5)	New educ. (6)
winner	0.0116*** (0.0027)	-0.0060*** (0.0015)	-0.0033*** (0.0011)			
Control mean	0.950	0.019	0.010			
N	64,781	64,781	64,781

Additional outcomes

Effect on U.S. Presence Grows Over Time

Raw means

But Firm Retention Effect Peaks in Year 1

Raw means

Taking Stock: Why Are Effects Small?

- Effects are statistically significant but moderate in the one-to-one sample (1.16 pp ↑ U.S. presence)
- **Reason 1:** Measurement error attenuates estimates
 - Probabilistic linkage mixes correct and incorrect matches
 - **How do effects vary by linkage quality?**
- **Reason 2:** OPT workers have fallback options
- **Reason 3:** Firms have other ways to retain workers
- **Reason 4:** Differential profile updating

Effects Robust Across Higher-Confidence Linked Samples

	In U.S.	Same firm
	(1)	(2)
One-to-one ($N = 64,781$)	0.0116*** (0.0027)	0.0264*** (0.0053)

$\hat{\beta}_1$ (winner effect) with SEs in parentheses; firm-by-lottery-year FE; SEs clustered by firm. $t = 1$ year post-lottery.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

$\hat{\beta}_1$ (winner effect) with SEs in parentheses; firm-by-lottery-year FE; SEs clustered by firm. $t = 1$ year post-lottery.

* $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

Control means

Taking Stock: Why Are Effects Small?

- Effects are statistically significant but moderate in the one-to-one sample (1.16 pp U.S. presence)
- **Reason 1:** Measurement error attenuates estimates
 - **Verdict:** Partial driver, but estimates still small in high-confidence samples
- **Reason 2:** OPT workers...use OPT?
 - Selecting on OPT $\implies$ applicants can continue to work through OPT!
 - **Prediction:** effects increase as OPT runs out
 - **How do effects vary by years since graduation?**
- **Reason 3:** Firms have other ways to retain workers
- **Reason 4:** Differential profile updating

Effects Strongest for Workers Near OPT Expiration

<i>Dependent Variable: In U.S.</i>				
	0 yrs post-grad (1)	1 yr post-grad (2)	2 yrs post-grad (3)	3 yrs post-grad (4)
winner	0.0089 (0.0129)	0.0150 (0.0094)	0.0158 (0.0099)	0.0520*** (0.0174)
Control mean	0.946	0.927	0.952	0.918
N	1,980	6,029	4,728	3,043

Outcome: In U.S. (1 year post-lottery). Cols (1)–(4): subgroups by years since graduation at time of lottery application.

** $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.*

Taking Stock: Why Are Effects Small?

- Effects are statistically significant but moderate in the one-to-one sample (1.16 pp U.S. presence)
- **Reason 1:** Measurement error attenuates estimates
 - **Verdict:** Partial driver, but estimates still small in high-confidence samples
- **Reason 2:** OPT workers...use OPT?
 - **Verdict:** Effects largest as applicants near OPT expiration, but still small even for those 3 years post-grad
- **Reason 3:** Firms have other ways to retain workers
 - Firms can re-sponsor lottery losers in subsequent years
 - **Prediction:** effects smaller at firms more likely to re-sponsor (*high-rep*)
 - **How do effects vary by employer type?**
- **Reason 4:** Differential profile updating

Sample Sizes Too Small to Detect Effects

Taking Stock: Why Are Effects Small?

- Effects are statistically significant but moderate in the one-to-one sample (1.16 pp U.S. presence)
- **Reason 1:** Measurement error attenuates estimates
 - **Verdict:** Partial driver, but estimates still small in high-confidence samples
- **Reason 2:** OPT workers...use OPT?
 - **Verdict:** Effects largest as applicants near OPT expiration, but still small even for those 3 years post-grad
- **Reason 3:** Firms have other ways to retain workers
 - **Verdict:** Sample sizes too small
- **Reason 4:** Differential profile updating
 - Winners may update LinkedIn more actively, inflating observed U.S. presence
 - **Prediction:** winners show more activity updates; location effects driven by profile changes, not actual stays
 - **How does profile updating vary by lottery outcome?**

Winners Update Profiles Less not More

	Activity update diff (1)	Profile in U.S. (2)	Profile home country (3)	Profile non-U.S. (4)	Profile loc. null (5)
winner	1.1155** (0.4624)				
Control mean	17.01				
N	64,712				

*OLS estimates; one-to-one linked sample; firm-by-lottery-year FE; SEs clustered by firm. $t = 1$ year post-lottery. Cols (2)–(5): profile location outcomes. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.*

And Location Effects Hold With Alternate Measure

	Activity update diff (1)	Profile in U.S. (2)	Profile home country (3)	Profile non-U.S. (4)	Profile loc. null (5)
winner	1.1155** (0.4624)	0.0152*** (0.0038)	-0.0087*** (0.0024)	-0.0143*** (0.0032)	-0.0009 (0.0022)
Control mean	17.01	0.885	0.051	0.083	0.031
N	64,712	64,781	64,781	64,781	64,781

*OLS estimates; one-to-one linked sample; firm-by-lottery-year FE; SEs clustered by firm. $t = 1$ year post-lottery. Cols (2)–(5): profile location outcomes. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.*

Outline

1. Introduction
2. Background and Context
3. Data and Linkage
4. Results
5. Conclusion

Conclusion

- **Main effects:** winning H-1B raises U.S. presence (+1.16 pp) and firm retention (+2.64 pp)
- **Magnitude of effects:** not fully explained by measurement error or OPT
- **Policy Implication/Puzzle:** OPT workers managing to remain without H-1B — how?

Next Steps:

- Explore more mechanisms: underreporting on LinkedIn, L-1 (intra-firm transfer), heterogeneity in school result
- Firm-level effects: benchmarking my estimates with literature

Thank You!
